

Subject: How does the covid estimate (incidence) work?

I'd like to know the full method. But specifically, there are some questions I can't find answers to.

Regarding the current method, described here: <https://covid.joinzoe.com/post/future-proofing-our-covid-estimates>

In the intermediate step, where ZOE estimates the risk reduction from vaccines:

1. Is it estimated separately for 3 doses of vaccine v.s. 2 doses?
2. Is it estimated separately in different age groups? If so, what are the age groups? I guess it would be a smaller number of different age groups than before, because you needed to increase the sample size?
3. And/or is it estimated over a longer time frame, than the 14 day period it was effectively estimated for in the previous method?

Thanks!
Alan
